V Accumulation of vitamins C and P in wild rose hips.  
A. Yadova and V. A. Pliner. Trudy Vsesoyuz. Nauch-

(I) content of wild rose hips in the early stages of the vegetative period is 1.44-1.72% on the wet and 4.0-5.6% on the dry basis. It reaches a max. of 2.80-3.32% and 11.30-12.30% resp., at the end of the vegetative period. During the post-vegetative period, I is reduced to a min. of 1.82-1.76% and 3.74-4.08% on the wet and dry bases, resp. At full maturity I rises again. Vitamin C (II) rises gradually during the vegetative period and reaches its max. at maturity. The presence of I in the leaves of wild roses can be demonstrated only by a special procedure. (The following values are all on the dry-wt. basis.) It can be as high as 3.0%, that of II only 0.9%, while in the stems it varies from 1.5-6.9%. Both I and II varied, though not in a parallel manner, I from 0.9% in *Rosa albertii* to 14.2% in *R. canina* and II from 1.05% in *R. spinosissima* to 9.78% in *R. rugosa*. A high I content (4.82-14.18%) and a low II content (1.56-2.86%) were found in *R. cinnamomea*, *R. laxa*, and *R. elliptica*. A low I content (0.9-2.15%) and a high II (8.91-9.78%) in *R. beggeriana*, *R. webbiana*, *R. rugosa*, *R. pomifera*, *R. hispida*, *R. spinosissima*, and *R. foetida*. The total sugar content in all varied from 12-27% and had no relation to either II or I.

no. 11, 1962, 5, abstract 11-3-10ye (Izv. Leningr.  
elektrotekhn. in-ta, no. 46, 1961, 337-339)

TEXT: The author considers the interaction processes of electrons  
with atoms and ions in a gaseous discharge, using the approximation  
of interaction in pairs; collective effects are not taken into ac-  
count here. It is shown that when any mechanism establishes a Max-  
well distribution of electron velocities, the radial field after a  
certain very short interval of time will set up a Boltzmann dis-  
tribution of the electrons in the space coordinates. The intial  
factor that establishes the velocity distribution of the electrons  
may be merely the interaction between them. 1 reference. Abstrac-

("Izv. Leningr. elektrotekhn. in-ta", 1961, no. 46, 303 - 307)

TEXT: The electrostatic energy of a substance (crystalline or amorphous) conserving the polarized state after removal of the external field is calculated on the assumption of the substance being comminuted into submacroscopic regions with different directions of polarization. The calculation is performed by taking account of both the presence of a free charge  $\sigma_f = -\alpha\sigma_g$ , where  $0 < \alpha < 1$ , which partly compensates the polarization charge on the interfaces, and the difference between the effective field in the boundary layer and the field in the bulk. It is found that there is a minimum of energy for a given dimension of the region, and that there is an equilibrium dimension of the region depending on  $\alpha$ . /B

ABSTRACT: A new sprayer nozzle design provides better operating characteristics with the following dimensions and condition parameters of the aluminum and sprayer: nozzle diameter - 26 mm; liquid jet diameter - 15 mm; air gap - 1.5--3.0 mm; pot temperature of Al - 710--750°C; pot pressure of Al - 2.5--3.0 kg/cm<sup>2</sup>; specific air flow rate - 0.19--0.24 kg/kg; sprayer pressure - 4--5 kg/cm<sup>2</sup>. With the fulfillment of the cited parameters the productivity of sprayer installations can reach 2100--2600 kg/hr, which exceeds by 45--95% the productivity of nozzles used in the factory up to 1962. The content of substandard fractions comprises 16--20%. G. Svodtseva (Translation of abstract)

TITLE: Manufacture of carbon-free vanadium alloys

SOURCE: Ref. zh. Metallurgiya, Abs. 11G214

REF SOURCE: Sb. tr. Klyuchevsk. z-da ferrosplavov, vyp. 1, 1965, 81--88

TOPIC TAGS: vanadium containing alloy, metal melting, iron containing alloy, aluminum containing alloy

ABSTRACT: It is reported that the most rational method for obtaining carbon-free V alloys is the aluminothermic method (0.02--0.06% C). The dependence of V extraction on the amount of reducing agent and other parameters was investigated. The Al content of the alloy should be kept below 1.5--2.0%. The smelting parameters of V alloys depend on the correct choice and amount of fluxes in the charge. The effect of lime in the slag was studied. The temperature dependence of the slag viscosity from Fe-V melts and the dependence of V extraction and Al content in the alloy were studied as a function of  $V_2O_5$  particle size.

TITLE: Silicothermic production of metallic chrome with partial melting of the oxides in the charge

PERIODICAL: Stal', no. 3, 1963, 226 - 227

TEXT: At the Klyuchevskiy zavod ferrosplavov (Klyuchevsk Plant in Ferro-alloys) a new technology has been established to produce low-carbon metallic chrome in the electric furnace. Before feeding in the reducing agents, 60 - 65% of chrome oxides is melted in the furnace with lime added, then the balance of oxides is fed in to the charge surface together with silicon crystals. The reduction process can take place with or without current. In the first case the silicon quantity added must ensure the formation of silicochrome containing at least 50% Si. The tests carried out with 30 kg chrome oxides yielded the following parameters: chrome-extraction: 84%; consumption of silicon crystals: 450 kg/t; power consumption: 2,600 kwh/t; silicon-utilization: 90%. The metal

Metallurgy of chrome ("Metallurgiya khroma"). Moscow, Izd-vo "Metallurgiya", 1965. 182 p. illus., biblio., tables., indices. Errata slip inserted. 1717 copies printed.		
TOPIC TAGS: chromium, chromium bearing ore, metallic chromium production, thermochemical chromium production, aluminum reduction, silicon reduction, chromium oxide reduction, chromium chloride reduction		
PURPOSE AND COVERAGE: This book is intended for engineering personnel of metallurgical plants and scientific research institutes. The book reviews the theoretical fundamentals of producing metallic chromium by various thermochemical methods including electrolytic and other methods. The characteristics of chromium-bearing ores are presented, and methods of producing chromium compounds discussed. The physical and chemical properties of chromium are indicated and phase diagrams of systems of chromium with		10

chromium in an electric arc furnace

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya  
metallurgiya, no.5, 1962, 78-85

TEXT: The following modified technology was investigated:  
preliminary melting of a part of the chromium oxide charge with  
addition of lime in an electric arc furnace, lifting the  
electrodes, adding the remaining part of the charge and finishing  
the process in the usual way. A part of the thermal energy is  
supplied by the electric arc, thus reducing the consumption of  
aluminium and eliminating the need for potassium nitrate (except  
for a small amount used for the initial ignition). In addition,  
the quality of the metal produced can be improved, since a part  
of the carbon present in chromium oxide will become oxidised, so  
that metal with a lower C and N content can be obtained. The  
experiments were carried out in an open semi-industrial arc

TITLE:

The Technology for Producing Carbon-Free Ferrochrome of High Nitrogen  
Content by the Aluminothermic Process

PERIODICAL: Stal', 1960, No. 9, pp. 817-818

TEXT: In the aluminothermic process for producing ferrochrome of high nitrogen content, which was developed by A.M. Samarin and S.I. Filippov, in 1945-46, the charge contains chrome ore concentrate, aluminum powder, sodium nitrate and slag obtained while melting chromium metal. In connection with the ever increasing number of steel types alloyed with nitrogen, it was found expedient to develop a more economical method for producing this kind of steel and to improve its properties as well as to raise the nitrogen content in the nitrified ferrochrome outside of the furnace. The main factors affecting the assimilation of nitrogen by ferrochrome in the aluminothermic process were investigated at the Klyuchevsk Plant. The nitrogen content of ferrochrome depends in the first place on the amount of nitrogen separated during melting, i.e., on the amount of salt-peter added to the charge. Melting tests were carried out with a salt-peter con-

the Aluminothermic Process

tent of 20-65 % of the weight of chromium concentrate and grinding and sieving the materials contained in the charge to a size of 0.8 mm. The necessary specific heat of the process ( $\delta H = 670$  cal/kg of the charge) was maintained by controlling the slag content. Maximum nitrogen content could be obtained by adding 40-45 % saltpeter based on the chrome concentrate. In order to determine the optimum granular size for obtaining a maximum nitrogen content in the alloy, tests were made with a constant 45 %-saltpeter content and by changing the granular size of the charge materials to a maximum of 2 mm, which, however, resulted in a decrease in the nitrogen content by 0.3 % on an average while the metal yield decreased by more than 20 %. The amount of deoxidizing agents affects the metal yield and the melting process. Tests carried out with 45 % saltpeter in the charge for the purpose of determining the optimum quantity of deoxidizing agents revealed that the maximum nitrogen content in the alloy is obtainable by applying deoxidizers in the amount of up to 97 % of the theoretical quantity of deoxidizers required for the process. In order to establish the optimum heat conditions tests were carried out with 670-750 cal/kg of the charge and it was found

by the Aluminothermic Process

that an increase in the specific heat of the process decreases the nitrogen content, while the maximum was obtained at a heat condition ensuring a specific heat of 670 cal/kg of the charge. Based on the test results a technology was developed for producing high-nitrogen, carbon-free ferrochrome, according to which 1.5-1.7 % nitrogen content can be obtained with 25 % saltpeter in the charge and with a specific heat of 625-635 cal/kg, whereas 2.0-2.1 % nitrogen content will be ensured with 45 % saltpeter in the charge and with a  $\delta H$  value of 670 cal/kg. There are 1 figure, 1 set of figures and 2 Soviet references.

TITLE: Material and heat-balance of smelting metallic chromium  
in an electric-arc furnace

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya  
metallurgiya, no. 2, 1962, 65 - 72

TEXT: A new method of chromium smelting, cheaper than the conventional process, had been proposed by the present authors and the object of the investigation described in the present paper was to check the efficiency of this process by compiling its material and heat-balances. The salient feature of the new process is the elimination from the charge of that portion of sodium nitrate which is normally used to provide heat required to ensure correct running of the smelting process and separation of the slag from the metal. In the new method a portion of oxides and fluxes constituting the total weight of the charge is fused in a three-phase electric-arc furnace and serves as a physical source of heat required in the reducing stage of the

Material and heat-balance ....

E193/E383

process. The smelting experiments were carried out in a 750 kVA furnace equipped with a magnetite-lined cast-iron melting shaft, provision having been made for insertion of several thermocouples. The temperature of the charge was measured from the moment of ignition of the combustible mixture added to the charge to form a liquid phase. When this had been formed, the furnace electrodes were lowered, current was switched on and the chromium oxide/lime mixture was smelted. The electrodes were then withdrawn and the reducing portion of the charge (chromium oxide and aluminium in the quantity required to reduce both the solid and fused oxides) was introduced into the melt. The composition of the charge, divided into igniting, ore-bearing and reducing portions (denoted by A, B and C, respectively) is given below:(kg):

Card 2/8

Material and heat-balance ....

The 767.8 kg Al used up in the process was made up as follows: 763.3 kg for reducing the chromium oxide, 3.48 kg and 0.92 kg for the reduction of silicon and iron, respectively, and 3.5 kg included in the metal produced. The process yielded 1 456 kg of crude chromium (Cr 99.06%, Si 0.24%, Al 0.24%, Fe 0.41%, C 0.019%, S 0.016%, P 0.007%), equivalent to 91.6% recovery, the degree of utilization of Al being 94.4%. Regarding the heat-balance, the total duration of the process was 1 hour 44 min, of which 1 hour 27 min constituted the smelting stage (with the current switched on) and the remainder represented the duration of the reducing stage. The temperature of the melt was 1 870 °C, the temperature of the process being 2 100 °C. The integrated heat-balance calculated for these conditions was as follows:

Translation from: Referativnyy zhurnal, Metallurgiya, 1958, Nr 10, p 28 (USSR)

AUTHOR: Pliner, Yu.L.

TITLE: Effect of Heating of a Charge and of Electrical Heating of Molten Slags Upon Performance Indices in the Aluminothermal Smelting of Ferrotitanium (Vliyanie nagreva shikhty i elektropodogreva zhidkikh shlakov na pokazateli aluminotermicheskoy vyplavki ferrotitana)

PERIODICAL: Izv. Sibirsk. otd. AN SSSR, 1958, Nr 1, pp 56-62

ABSTRACT: Experimental laboratory and industrial heats of Fe-Ti are made by the aluminothermal method, with heating of the charge. They show that the yield of metal under these conditions rises by 7-8%, the Al consumption being reduced from 540 to 490 kg/t. It is found that as the quantity of charge increases, the temperature to which it has to be heated diminishes and is 215°C for the smelting of 1500 kg of concentrate. An investigation of the slags showed that when the charge is heated, its Fe-Ti-beads content diminishes considerably. Experimental pilot-plant heats with electrical heating of the molten slag by immersion of the electrodes of a 3-phase arc furnace into it to a depth of

TITLE: Estimate of the Rate of Sinking of Ferrotitanium Drops in Molten Slag

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 135, No. 5,  
pp. 1167-1169

~~REMARKS~~ The authors report on the investigation of the loss of ferrotitanium in slag during aluminothermal melting. They recommend measurements for the elimination of such losses (up to 10% of the total weight). The time during which the slag remains liquid is too short for the complete sinking of drops in the slag (Ref. 1). In Ref. 2, the authors mention that

the motion of one drop has the following velocity:  $V = V_0 \frac{3\eta + 3\eta' + \epsilon x}{2\eta + 3\eta' + \epsilon x}^{2-1}$  (1)

where  $V_0$  denotes the velocity of motion of a solid ball of the same radius as the drop;  $\eta$  is the viscosity of the slag;  $\eta'$  is the viscosity of the metal drop;  $\epsilon$  is the charge per unit area of the drop; and  $x$  is the elec-

Card 1/4

Estimate of the Rate of Sinking of Ferrotitanium  
 titanium Drops in Molten Slag

B016/B052

trical conductivity of the slag. Since practically no retardation of the tangential motion of the liquid within the drop takes place when

$\eta + \eta' \gg \epsilon^2 x^{-1}$ , equation (1) (considering that  $\eta \gg \eta'$ ) takes the form of  $V = 3/2 V_0$  (2). After comparing published data (V. V. Khlynov and

C. A. Yesin, Ref. 4) with the viscosity of ferrotitanium slag (4.8 poise), the authors suggest the following approximate equation for the velocity of motion of the metal drop in the slag:  $V = \frac{V_0 + 3/2 V_0}{2} = 1.25 V_0$  (3), or

$V = 1.25 \cdot 2/9 \cdot \frac{r^2 (\gamma_2 - \gamma_1)}{\eta} = 272.5 \frac{r^2 (\gamma_2 - \gamma_1)}{\eta}$  (4), where  $r$  is the radius of the drop,  $\gamma_2$  and  $\gamma_1$  are the density of drop and slag, respectively. A comparison of the grain size of scrap aluminum (0.42 mm) used formerly with that of the metal drop in the slag ( $0.36 \pm 0.03$  mm) showed that they are practically equal. Fig. 1 shows the viscosity of slag between 1450 and 1750°C measured with an electromagnetic vibrating viscosimeter. A

Card 2/4

S/020/60/135/005/037/043  
B016/B052

thermocouple of the type UMMUM-1 (TsNIIChM-1), designed at the Central Scientific Institute of Ferrous Metallurgy was used for measuring temperature. The considerably high viscosity at high temperatures is due to the presence of slightly mobile ions mainly of  $\text{AlO}_2^-$  (Ref. 6). Equation (4) can only be applied for the sinking rate of drops as long as the motion remains laminar. This is only the case until the critical rate of

$$V = c \frac{1}{\sqrt{2} \cdot r} \quad (5)$$

is reached (where  $c$  is the Reynolds criterion). The au-

thors combine equations (4) and (5) to obtain the maximum value of the drop radius at which the motion is still laminar, namely:  $r_{\max} = 0.97 \text{ cm}$ . Since this value exceeds considerably the size of metal drops formed during reduction, the authors calculate the sinking rate of the ferrotitanium drops. From these data they conclude that only drops larger than 0.2 mm can sink down to the metal layer. Drops with a radius of 0.05 mm and less are practically all kept back in the slag. For the elimination of losses, the authors suggest: a) the use of aluminum shot with a grain size of 0.1 - 0.2 mm; b) melting in a heated forge or in an electric furnace of

Pilka, J.; and Watanuki, T. A uniqueness condition with a standard differential equation without uniqueness property. Bull. Acad. Polon. Sci. Sér. Sci. Math. Astr. Phys., 6 (1958), 145-148.

In the system (1)  $X' = F(t, X)$  a solution  $X = X(t)$  ( $a < t < b$ ) will be called unique to the right if, for any solution  $Y(t)$  of (1) defined in  $y \leq t \leq b$ ,  $a < y < d < b$ , and satisfying  $Y(y) = X(y)$ , we have  $Y(t) = X(t)$ ,  $y \leq t \leq b$ . The main theorem also requires the following definition: We say that a function  $g(t, x)$  defined in a subset  $S$  of the half-plane  $x > 0$  has property  $P$  if for every real number  $s$  there exists a sequence  $x_n(t)$  of positive solutions of  $x' = g(t, x)$  such that either (I) there exists  $\epsilon > 0$  such that  $\lim_{n \rightarrow \infty} x_n(t) = 0$  for  $s \leq t \leq s + \epsilon$ , or (II) there exists a sequence of numbers  $t_n > s$ ,  $t_n \rightarrow s$  as  $n \rightarrow \infty$ , and for each fixed  $n$ ,  $x_n(t) \rightarrow 0$  as  $t \rightarrow t_n$  ( $s < t < t_n$ ).

Theorem: Suppose that the right hand members of the system (1), defined in the open set  $R$ , satisfy the inequality

$$|F(t, X) - F(t, Y)| < g(t, |X - Y|)$$

for  $(t, X) \in R$ ,  $(t, Y) \in R$ ,  $(t, X - Y) \in S$ ,  $|A| = (a_1^2 + a_2^2 + \dots + a_n^2)^{1/2}$ , where the function  $g(t, x)$  has property  $P$ . Then every solution of (1) is unique to the right.

PI 1s, A

Plis A. Sets filled by asymptotic integrals of ordinary differential equations. Bull. Acad. Polon. Sci. Cl. III. 4 (1956), 749-752.

The author considers the system of  $k+m$  real ordinary differential equations

(1)  $\dot{x} = f(x, y, t), \dot{y} = g(x, y, t),$

where  $x = (x_1, \dots, x_k)$ ,  $y = (y_1, \dots, y_m)$ ,  $f = (f^1, \dots, f^k)$ ,  $g = (g^1, \dots, g^m)$ . It is assumed that  $f$  and  $g$  are continuous

in an open set  $S$  of  $(k+m+1)$ -space, and therein satisfy certain unusual inequalities. Also it is assumed that (1) has a unique solution for each initial point in  $S$ . Let  $U$  be the set of points  $(X, Y, T)$  lying on solution curves of (1) which remain in  $S$  for  $T \leq t < \infty$  and which also satisfy a certain growth condition. The principal theorem states that  $U$  is the graph of a single-valued Lipschitz function  $Y = v(X, T)$ .

Plis A. On the problem of non-local existence for first  
integrals of a system of ordinary differential equations. I - F/F

Bull. Acad. Polon. Sci. Cl. (11), 3, 31-37 (1955).

An example is given of a system  $(S)$ :  $\dot{x}^j = f_j(x, y)$ ,  
( $j=1, 2$ ) with  $f_j \in C^\alpha$  in  $E$ , such that if  $s(x, y)$  is continuous in  $E$ , and is constant on the integrals of  $(S)$  then  $s$  is constant throughout  $E$ .  $(S)$  is constructed in such a way that its integral of ramification (in the sense of Wazewski) is dense in  $E$ .

J.F.W.  
L'Ann. A  
domaine  
(1956)  
Remarque sur le système dynamique dans le  
doublement connexe. Ann. Polon. Math. 3  
169-171.

This paper is in the line of the Wazewski's topological  
theory (see e.g. T. Wazewski, same Ann. 17 (1955), 339-  
345; MR 17, 611; Z. Mikolajka, ibid. 1 (1955) 277-305;  
J. M. A. Pisz, Bull. Acad. Polon. Sci. Cl. III 3  
(1954), 315-318; MR 16, 700; R. Albrecht, ibid. 2 (1954),  
315-318; MR 16, 248) and concerns the differential system  
 $(*) \frac{dx}{dt} = X(x, y), \frac{dy}{dt} = Y(x, y)$ , where  $X, Y$  are continuous  
functions in the whole  $xy$ -plane and a uniqueness  
theorem holds. An annular region  $G$  is considered lying  
between two simple closed curves  $C_1, C_2$ , and the following  
hypotheses are made concerning the set  $S$  of the points  
of egress from  $G$ : all points of  $S$  are points of strict egress;  
 $S \neq C_1, S \neq C_2, S \neq 0, S \neq C_1 + C_2$ . Under these hypotheses  
there exists in  $G$  at least one singular point for  $(*)$ ; i.e., a  
point where  $X = Y = 0$ .
